The RBC Model - Using DYNARE

Winter 2015

Queen's University - ECON 815

RBC Model

We can write our RBC model as

$$\begin{aligned} \theta(1-n_t)^{-\eta} &= (1-\alpha)\frac{y_t}{n_t}c_t^{-\gamma} \\ c_t^{-\gamma} &= \beta E_t \left[c_{t+1}^{-\gamma} \left(\alpha \frac{y_{t+1}}{k_{t+1}} + (1-\delta) \right) \right] \\ c_t + k_{t+1} &= y_t + (1-\delta)k_t \\ y_t &= z_t k_{t+1}^{\alpha} n_t^{1-\alpha} \\ \log z_t &= \rho \log z_{t-1} + \epsilon_t \end{aligned}$$

We have four endogenous variables we want to look at:

- \blacktriangleright output y
- \blacktriangleright labour supply n
- \blacktriangleright consumption c
- \blacktriangleright capital k

Model in DYNARE - Logs

Some equations:

$$\begin{aligned} & \texttt{theta} * (1 - \texttt{exp(lab)})^{(-\texttt{eta})} = \dots; \\ & \texttt{exp(c)}^{(-\texttt{gam})} = \texttt{bet} * \texttt{exp(c(+1))}^{(-\texttt{gam})} * \dots; \\ & \texttt{exp(c)} + \texttt{exp(k)} = \texttt{exp(y)} + (1 - \texttt{delta}) * \texttt{exp(k(-1))}; \\ & \texttt{exp(y)} = \texttt{exp(z)} + \texttt{alpha} * \texttt{exp(k(-1))}^{\alpha} * \texttt{exp(lab)}^{(1 - \texttt{alpha})}; \\ & \texttt{z} = \texttt{rho} * \texttt{z}(-1) + \texttt{e}; \end{aligned}$$

Important issues:

- ▶ model will treat variables in logs -z is in logs already, c is log c
- decision (jump) variables have current index
- state variables in period t have index -1
 - ▶ k(-1) is capital just before period t
 - ▶ z(-1) is productivity just before shock in period t
- ▶ forward looking variables are treated in expectations

Policy Functions

The solution of the linearized model is in <u>percentage deviations</u> from steady state.

$$k_{t+1} = \bar{k} + a_1(k_t - \bar{k}) + a_2(z_t - \bar{z})$$

The interpretation in DYNARE of the coefficients is according to

$$\mathtt{k}=\bar{\mathtt{k}}+\mathtt{a}_1(\mathtt{k}(-1)-\bar{\mathtt{k}})+\mathtt{a}_2(\mathtt{z}(-1)-\bar{\mathtt{z}})+\mathtt{a}_3\mathtt{e}.$$

so that $a_1 = a_1$, $a_2 = \rho a_2$ and $a_3 = a_2$.

Hence, the solution distinguishes between the effects of the current shock and the lagged term from the AR(1) shock process.

Beyond this, DYNARE delivers

- impulse response functions
- autocorrelations
- second order moments

Correlations

MATRIX OF CORRELATIONS

Variables	У	с	k	lab	Z
У	1.0000	0.9220	0.8357	0.6758	0.9950
с	0.9220	1.0000	0.9832	0.3377	0.8788
k	0.8357	0.9832	1.0000	0.1599	0.7767
lab	0.6758	0.3377	0.1599	1.0000	0.7460
\mathbf{Z}	0.9950	0.8788	0.7767	0.7460	1.0000

COEFFICIENTS OF AUTOCORRELATION

Order	1	2	3	4	5
У	0.9659	0.9327	0.9005	0.8691	0.8387
с	0.9943	0.9866	0.9772	0.9661	0.9536
k	0.9986	0.9948	0.9888	0.9808	0.9710
lab	0.8999	0.8075	0.7224	0.6439	0.5716
\mathbf{Z}	0.9562	0.9143	0.8743	0.8360	0.7994

Match with Data

Golden ratios?

▶ c/y = 0.79 and k/y = 8.26 from calibration

Covariance with output?

▶ labour -0.67 vs. 0.7 (data); consumption -0.92 vs. 0.53 (data)

Standard deviations

Variables	SD	% of SD(y)
У	0.0275	1
с	0.0215	0.78
k	0.0284	1.03
lab	0.0079	0.28
Z	0.0164	0.60

Compared to the data?

- labour/output 28% vs. 97% (data)
- consumption/output 78% vs. 72% (data)
- ▶ output model explains 92% of SD in the data [check]

Critique – No Amplification

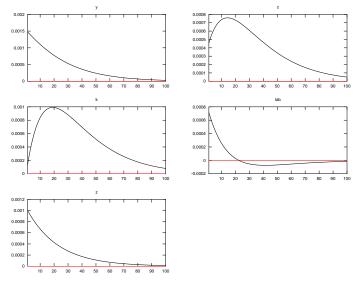

Figure : Low shocks - Canadian Data

Critique – No Propagation

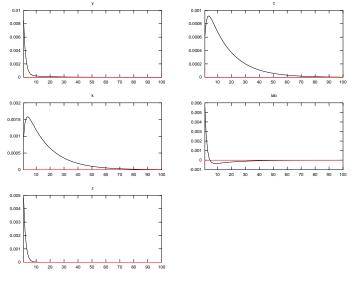

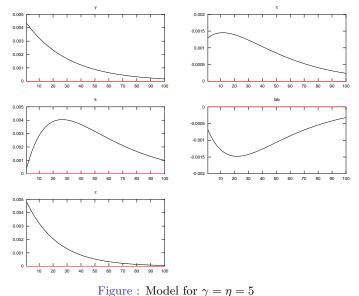

Figure : Low autocorrelation – Canadian Data

Critique – Labour Supply Elasticity

Labour Elasticity (cont.)

We have in the model

$$l_t + n_t = 1$$

$$\theta l_t^{-\eta} = \lambda(z_t) w_t$$

where l_t is leisure and η is the Frisch elasticity of labour supply.

Log-linearizing, we obtain

$$\hat{n}_t = \frac{\bar{l}}{\bar{n}} \frac{1}{\eta} \left(\hat{w}_t + \hat{\lambda}_t \right)$$

For $\eta = 1$ and $\bar{l} = 0.8$, we obtain a huge response of labour supply to changes in wages. Empirically, this is not the case.

The model fits best for the linear labour model which we interpret as (efficient!) changes in (un)employment.

Queen's University - ECON 815

Summary

Ken Rogoff:

"The real business cycle results..., are certainly productive. It has been said that a brilliant theory is one which at first seems ridiculous and later seems obvious. There are many that feel that (RBC) research has passed the first test. But they should recognize the definite possibility that it may someday pass the second test as well."

My assessment:

It shows the power of the DSGE approach. But it would be foolish to think that business cycles are entirely driven by highly persistent technology shocks and the large – and efficient – reaction of labor input to such shocks.

The RBC model is particularly "vulnerable" to changes in the intertemporal elasticity of substitution. But one can argue that this is precisely what we are most interested in (employment responses).
